

Installation

MongoDB

Mongodb, is a non-relational or No-SQL db. The reason why it's included in MERN stack is, everything is JS in mongodb. The database itself is written in C++, but the language that is used to connect to DB, request data from DB, add new data to DB is JavaScript.

So thankfully you don't have to learn any new language to learn Mongodb. it makes learning mongo very easy.

Installation

MongoDB comes with 2 types, Enterprise and Community. the Community Edition is fully free and includes complete features of the database. Enterprise is the version that needs to pay, but it only includes "extra" features like 0% downtime etc. which are rarely needed for learning purpose.

head to [this link](#), Download the Community Edition based on your operating system, and install it. it will mostly be just double click and next -> next -> next etc.

MongoSh

The above link only installs the database itself. to connect with database, you will need another tool called as mongosh. install it from [here](#);

MongoDB Compass (GUI)

you will need another tool called as MongoDB compass for GUI . install it from [here](#);

Document

Every Single smallest unit you can store in the mongodb, is called as a document. a document is nothing but a object from JS. it's as simple as that. thus, { name: "john" } is a valid mongodb 'document' and you can store it in mongodb, and perform any operation on it.

Collection

A collection is just set of documents. if you have 10 users information you want to store in your database, So you can create a "collection", give it a name, and then store the documents in it. Collections only job is to group similar types of documents. (here you can give it a name like "users" then later it becomes easy to ask mongodb give me first 2 users from "users" collection)

Database

Above we collectively referred "database" as a software that manages your data. but once you have that software (here mongodb) installed, a database is usually referred to as "set of similar type of data". overall it's a Group of collections. eg: now you have Users collection that has documents on users personal information, you can create one more collection that stores users Employment information, call it, employee etc.

you can have multiple such databases.

-----+

-----+

For Window user type mongosh in command prompt

For Mac user type mongo in terminal
